

## BTU OUTPUT

Each panel has a different BTU output depending on the room temperature and input/output average temperature. Our standard BTU values are reported on a basis of 68F room temperature and a 108F  $\Delta T$  (Average Water Temperature Inlet/Outlet – Room temperature)

| Reference | $\Delta T$ 108F (BTU/H) |
|-----------|-------------------------|
| 11-500    | 1686                    |
| 11-1000   | 3368                    |
| 21-750    | 2546                    |
| 21-1500   | 5088                    |
| 22-900    | 3293                    |
| 22-1800   | 6583                    |
| 33-2500   | 9399                    |
| 11-850    | 2682                    |

Chart1: Standard Output

It is possible to obtain each individual radiator value following the information mentioned in one of the two charts showed below, applying correction factors or taking into account different water entrance temperatures.

| $\Delta T$ | BTU CORRECTION FACTOR |
|------------|-----------------------|
| 48         | 0,35                  |
| 53         | 0,40                  |
| 58         | 0,45                  |
| 63         | 0,50                  |
| 68         | 0,55                  |
| 73         | 0,60                  |
| 78         | 0,66                  |
| 83         | 0,71                  |
| 88         | 0,77                  |
| 93         | 0,82                  |
| 98         | 0,88                  |
| 103        | 0,94                  |
| 108        | 1,00                  |
| 113        | 1,06                  |
| 118        | 1,12                  |
| 123        | 1,18                  |

Chart3: Corrected values for different water entrance temperatures at constant 68F room temperature.

# PRESSURE DROP CALCULUS

Two factors are needed to size a circulator pump correctly. Gallons per minute (GPM) and system pressure drop (feet of head). Following the example on the next page, use the GPM value to calculate the pressure drop through the entire system to be able to correctly size the circulator pump.

Using the tables below, find the pressure drop the DKH2O has in feet of head.

To calculate GPM for a system circulator, use the following formula:

$$\text{GPM} = (\text{Total BTU/H}) / (500 \times \Delta T)$$

Which reads: GPM needed **equals** the total BTU's the circulator needs to provide **divided by 500 times** the temperature differential between the supply and return water temperatures. Normally, the target temperature differential is 20°. This is what we will use in our example.

**Example 1:**

We have (3) model DKH20 21-1500 with 190°F water entrance temperature. Each provides 5829 BTH/H (chart 3)

3 x 5829 BTU/H = 17487 BTU/H. Our ΔT will be 20°F (supply-return).

$$\text{GPM} = (\text{Total BTU/H}) / (500 \times \Delta T)$$

$$\text{GPM} = 17487 / (500 \times 20)$$

$$\text{GPM} = 17487 / 10000$$

$$\text{GPM} = 1.7487$$

Go to the second pressure drop chart and find 1.7487 GPM flow. Follow the chart up until you cross the pressure drop curve. Read the corresponding feet of head on the left. It is approximately 3.2 feet of head.

**Example 2:**

We have (1) model DKH20 11-1000, (1) model DKH20 21-1500 and (2) model DKH20 33-2500 with 200°F water entrance temperature.

4268 + 6471 + (2 x 12051) = 34841 BTU/H. Our ΔT will be 20°F (supply-return).

$$\text{GPM} = (\text{Total BTU/H}) / (500 \times \Delta T)$$

$$\text{GPM} = 34841 / (500 \times 20)$$

$$\text{GPM} = 34841 / 10000$$

$$\text{GPM} = 3.4841$$

With example 2, multiple models have been used and both charts need to be consulted. Pressure drop on the 11-1000 from the top chart is approximately 5 feet of head. Pressure drop on the other three units from the bottom chart is approximately 12 feet of head.

Knowing the head loss, keep this in mind when sizing a circulator: When piping in series, the pressure drop of all components are added together to determine total head loss (feet of head). When piping in parallel, the largest single head loss of all parallel components is used.
